Chapter 1

Classes

1.1 squarefree – Squarefreeness tests

- **Classes**
 - **Undetermined**
- **Functions**
 - **lenstra**
 - **trial_division**
 - **trivial_test**
 - **viafactor**
 - **lenstra_ternary**
 - **trivial_test_ternary**
 - **trial_division_ternary**
 - **viafactor_ternary**
 - **viadecomposition**

There are two method groups. A function in one group raises **Undetermined** when it cannot determine squarefreeness. A function in another group returns **None** in such cases. The latter group of functions have “_ternary” suffix on their names. We refer a set $\{\text{True}, \text{False}, \text{None}\}$ as *ternary*.

The parameter type *integer* means either int, long or **Integer**.

1.1.1 Definition

We define squarefreeness as:

n is squarefree \iff there is no prime p whose square divides n .

Examples:

- 0 is non-squarefree because any square of prime can divide 0.
- 1 is squarefree because there is no prime dividing 1.
- 2, 3, 5, and any other primes are squarefree.
- 4, 8, 9, 12, 16 are non-squarefree composites.
- 6, 10, 14, 15, 21 are squarefree composites.

1.1.2 Undetermined – undetermined state of calculation

This is an exception notifying undetermined state of calculation. The exception will be raised by **lenstra** or **trivial_test**.

1.1.3 lenstra

lenstra(*n: integer*) \rightarrow *bool*

If return value is True, *n* is squarefree. Otherwise, the squarefreeness is still unknown and **Undetermined** is raised. The algorithm is based on [1].

†The condition is so strong that it seems *n* has to be a prime or a Carmichael number to satisfy it.

Input parameter *n* ought to be an odd **integer**.

1.1.4 trial_division

trial_division(*n: integer*) \rightarrow *bool*

Check whether *n* is squarefree or not.

The method is a kind of trial division and inefficient for large numbers.

Input parameter *n* ought to be an **integer**.

1.1.5 trivial_test

trivial_test(*n: integer*) \rightarrow *bool*

Check whether *n* is squarefree or not. If the squarefreeness is still unknown, then **Undetermined** is raised.

This method do anything but factorization including Lenstra's method.

Input parameter *n* ought to be an odd **integer**.

1.1.6 viafactor

viafactor(*n: integer*) \rightarrow *bool*

Check whether *n* is squarefree or not.

It is obvious that if one knows the prime factorization of the number, he/she can tell whether the number is squarefree or not.

Input parameter *n* ought to be an **integer**.

1.1.7 `lenstra_ternary`

`lenstra_ternary(n: integer) → ternary`

Test the squarefreeness of `n`. The return value is one of the ternary logical constants. If return value is `True`, `n` is squarefree. Otherwise, the squarefreeness is still unknown and `None` is returned.

†The condition is so strong that it seems `n` has to be a prime or a Carmichael number to satisfy it.

This is a ternary version of `lenstra`.

Input parameter `n` ought to be an odd `integer`.

1.1.8 `trivial_test_ternary`

`trivial_test_ternary(n: integer) → ternary`

Test the squarefreeness of `n`. The return value is one of the ternary logical constants.

The method uses a series of trivial tests including `lenstra_ternary`. This is a ternary version of `trivial_test`.

Input parameter `n` ought to be an `integer`.

1.1.9 `trial_division_ternary`

`trial_division_ternary(n: integer) → ternary`

Test the squarefreeness of `n`. The return value is either one of `True` or `False`; `None` never be returned.

The method is a kind of trial division.

This is a ternary version of `trial_division`.

Input parameter `n` ought to be an `integer`.

1.1.10 `viafactor_ternary`

`viafactor_ternary(n: integer) → ternary`

Just for symmetry, this function is defined as an alias of `viafactor`.

Input parameter `n` ought to be an **integer**.

1.1.11 viadecomposition

viadecomposition(`n`: *integer*) \rightarrow *bool*

Test the squarefreeness of `n`. The return value is either one of `True` or `False`; `None` never be returned.

The method uses partial factorization into squarefree parts, if such partial factorization is possible. In other cases, It completely factor `n` by trial division.

Input parameter `n` ought to be an **integer**.
