# Chapter 1

## Functions

### 1.1 `factor.methods` – factoring methods

It uses methods of `factor.find` module or some heavier methods of related modules to find a factor. Also, classes of `factor.util` module is used to track the factorization process. `options` are normally passed to the underlying function without modification.

This module uses the following type:

**factorlist** :

`factorlist` is a list which consists of pairs (`base`, `index`). Each pair means  $base^{index}$ . The product of these terms expresses prime factorization.

#### 1.1.1 `factor` – easiest way to factor

```
factor(n: integer, method: string='default', **options )  
→ factorlist
```

Factor the given positive integer `n`.

By default, use several methods internally.

The optional argument `method` can be:

- `'ecm'`: use elliptic curve method.
- `'mpqs'`: use MPQS method.
- `'pmom'`: use  $p - 1$  method.
- `'rhomethod'`: use Pollard's  $\rho$  method.
- `'trialDivision'`: use trial division.

(†In fact, the initial letter of method name suffices to specify.)

### 1.1.2 ecm – elliptic curve method

```
ecm(n: integer, **options) → factorlist
```

Factor the given integer  $n$  by elliptic curve method.

(See **ecm** of **factor.ecm** module.)

### 1.1.3 mpqs – multi-polynomial quadratic sieve method

```
mpqs(n: integer, **options) → factorlist
```

Factor the given integer  $n$  by multi-polynomial quadratic sieve method.

(See **mpqsfind** of **factor.mpqs** module.)

### 1.1.4 pmom – $p - 1$ method

```
pmom(n: integer, **options) → factorlist
```

Factor the given integer  $n$  by  $p - 1$  method.

The method may fail unless  $n$  has an appropriate factor for the method.  
(See **pmom** of **factor.find** module.)

### 1.1.5 rhomethod – $\rho$ method

```
rhomethod(n: integer, **options) → factorlist
```

Factor the given integer  $n$  by Pollard's  $\rho$  method.

The method is a probabilistic method, possibly fails in factorizations.  
(See **rhomethod** of **factor.find** module.)

### 1.1.6 trialDivision – trial division

```
trialDivision(n: integer, **options) → factorlist
```

Factor the given integer `n` by trial division.

`options` for the trial sequence can be either:

1. `start` and `stop` as range parameters.
2. `iterator` as an iterator of primes.
3. `eratosthenes` as an upper bound to make prime sequence by sieve.

If none of the options above are given, the function divides `n` by primes from 2 to the floor of the square root of `n` until a non-trivial factor is found.  
(See `trialDivision` of `factor.find` module.)

### Examples

```
>>> factor.methods.factor(10001)
[(73, 1), (137, 1)]
>>> factor.methods.ecm(1000001)
[(101L, 1), (9901L, 1)]
```
