Chapter 1

Classes

- 1.1 poly.termorder hoge class object
 - Classes
 - $-\ \dagger TermOrderInterface$
 - $-\ \dagger Univar Term Order$
 - MultivarTermOrder

1.1.1 TermOrderInterface – interface of term order

Initialize (Constructor)

$TermOrderInterface(comparator: function) \rightarrow TermOrderInterface$

A term order is primally a function, which determines precedence between two terms (or monomials). By the precedence, all terms are ordered.

More precisely in terms of Python, a term order accepts two tuples of integers, each of which represents power indeces of the term, and returns 0, 1 or -1 just like cmp built-in function.

A TermOrder object provides not only the precedence function, but also a method to format a string for a polynomial, to tell degree, leading coefficients, etc.

comparator accepts two tuple-like objects of integers, each of which represents power indeces of the term, and returns 0, 1 or -1 just like cmp built-in function.

This class is abstract and should not be instantiated. The methods below have to be overridden.

Methods

1.1.1.1 cmp

```
	ext{cmp(self, left: } \textit{tuple}, 	ext{ right: } \textit{tuple}) 
ightarrow \textit{integer}
```

Compare two index tuples left and right and determine precedence.

1.1.1.2 format

Return the formatted string of the polynomial polynom.

1.1.1.3 leading coefficient

```
\textbf{leading coefficient(self, polynomial)} \rightarrow \textit{CommutativeRingElement}
```

Return the leading coefficient of polynomial polynom with respect to the term order.

1.1.1.4 leading term

```
leading term(self, polynom: polynomial) → tuple
```

Return the leading term of polynomial polynom as tuple of (degree index, coefficient) with respect to the term order.

1.1.2 UnivarTermOrder – term order for univariate polynomials

Initialize (Constructor)

```
{f Univar Term Order (	ext{comparator: } function) 
ightarrow Univar Term Order}
```

There is one unique term order for univariate polynomials. It's known as degree.

One thing special to univariate case is that powers are not tuples but bare integers. According to the fact, method signatures also need be translated from the definitions in TermOrderInterface, but its easy, and we omit some explanations.

comparator can be any callable that accepts two integers and returns 0, 1 or -1 just like cmp, i.e. if they are equal it returns 0, first one is greater 1, and otherwise -1. Theoretically acceptable comparator is only the cmp function.

This class inherits **TermOrderInterface**.

Methods

1.1.2.1 format

```
\begin{array}{lll} & \textbf{format(self, polynomial, varname: } \textit{string} = \text{'X', reverse: } \\ & bool = \textbf{False}) \\ & \rightarrow \textit{string} \end{array}
```

Return the formatted string of the polynomial polynom.

- polynom must be a univariate polynomial.
- varname can be set to the name of the variable.
- reverse can be either True or False. If it's True, terms appear in reverse (descending) order.

1.1.2.2 degree

```
\texttt{degree}(\texttt{self}, \, \texttt{polynom} ial) \rightarrow integer
```

Return the degree of the polynomial polynom.

1.1.2.3 tail degree

```
	ext{tail degree(self, polynom}: polynomial)} 
ightarrow integer
```

Return the least degree among all terms of the polynom.

This method is experimental.

1.1.3 MultivarTermOrder – term order for multivariate polynomials

Initialize (Constructor)

```
\operatorname{MultivarTermOrder}(\operatorname{comparator}: function) 	o MultivarTermOrder
```

This class inherits **TermOrderInterface**. Though this class is the main purpose of the module, descriptions of every methods are identical to the base class.
